# Section 5: Dummy Variables and Interactions 

Carlos M. Carvalho<br>The University of Texas at Austin<br>McCombs School of Business

http://faculty.mccombs.utexas.edu/carlos.carvalho/teaching/

## Example: Detecting Sex Discrimination

Imagine you are a trial lawyer and you want to file a suit against a company for salary discrimination... you gather the following data...

| Gender |  | Salary |
| :--- | :---: | :---: |
| 1 | Male | 32.0 |
| 2 | Female | 39.1 |
| 3 | Female | 33.2 |
| 4 | Female | 30.6 |
| 5 | Male | 29.0 |
| $\ldots$ | $\ldots$ |  |
| . . . |  |  |
| 208 | Female | 30.0 |

## Detecting Sex Discrimination

You want to relate salary $(Y)$ to gender $(X) \ldots$ how can we do that?

Gender is an example of a categorical variable. The variable gender separates our data into 2 groups or categories. The question we want to answer is: "how is your salary related to which group you belong to..."

Could we think about additional examples of categories potentially associated with salary?

- MBA education vs. not
- legal vs. illegal immigrant
- quarterback vs wide receiver

## Detecting Sex Discrimination

We can use regression to answer these question but we need to recode the categorical variable into a dummy variable

| Gender |  | Salary | Sex |
| :--- | ---: | ---: | :---: |
| 1 | Male | 32.00 | 1 |
| 2 | Female | 39.10 | 0 |
| 3 | Female | 33.20 | 0 |
| 4 | Female | 30.60 | 0 |
| 5 | Male | 29.00 | 1 |

208 Female 30.000
Note: In Excel you can create the dummy variable using the formula:

$$
=\mathrm{IF}(\text { Gender }=\text { "Male", } 1,0)
$$

## Detecting Sex Discrimination

Now you can present the following model in court:

$$
\text { Salary }_{i}=\beta_{0}+\beta_{1} \text { Sex }_{i}+\epsilon_{i}
$$

How do you interpret $\beta_{1}$ ?

$$
\begin{aligned}
& E[\text { Salary } \mid \text { Sex }=0]=\beta_{0} \\
& E[\text { Salary } \mid \text { Sex }=1]=\beta_{0}+\beta_{1}
\end{aligned}
$$

$\beta_{1}$ is the male/female difference

## Detecting Sex Discrimination

$$
\text { Salary }_{i}=\beta_{0}+\beta_{1} \text { Sex }_{i}+\epsilon_{i}
$$

| Regression Statistics |  |
| :--- | ---: |
| Multiple R | 0.346541 |
| R Square | 0.120091 |
| Adjusted R Square | 0.115819 |
| Standard Error | 10.58426 |
| Observations | 208 |

ANOVA

|  | $d f$ |  | SS | MS | $F$ |
| :--- | ---: | :---: | :---: | :---: | ---: |
| Regression | 1 | 3149.634 | 3149.6 | 28.1151 | Significance $F$ |
| Residual | 206 | 23077.47 | 112.03 |  |  |
| Total | 207 | 26227.11 |  |  |  |

|  | Coefficientstandard Errı |  |  |  |  |  |  | $t$ Stat | P-value | Lower 95\% | Upper 95\% |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Intercept | 37.20993 | 0.894533 | 41.597 | 3E-102 | 35.44631451 | 38.9735426 |  |  |  |  |  |
| Gender | 8.295513 | 1.564493 | 5.3024 | $2.9 \mathrm{E}-07$ | 5.211041089 | 11.3799841 |  |  |  |  |  |

$\hat{\beta}_{1}=b_{1}=8.29 \ldots$ on average, a male makes approximately $\$ 8,300$ more than a female in this firm.

How should the plaintiff's lawyer use the confidence interval in his presentation?

## Detecting Sex Discrimination

How can the defense attorney try to counteract the plaintiff's argument?

Perhaps, the observed difference in salaries is related to other variables in the background and NOT to policy discrimination...

Obviously, there are many other factors which we can legitimately use in determining salaries:

- education
- job productivity
- experience

How can we use regression to incorporate additional information?

## Detecting Sex Discrimination

Let's add a measure of experience...

$$
\text { Salary }_{i}=\beta_{0}+\beta_{1} \text { Sex }_{i}+\beta_{2} \text { Exp }_{i}+\epsilon_{i}
$$

What does that mean?

$$
\begin{aligned}
& E[\text { Salary } \mid \text { Sex }=0, \text { Exp }]=\beta_{0}+\beta_{2} E x p \\
& E[\text { Salary } \mid \text { Sex }=1, \text { Exp }]=\left(\beta_{0}+\beta_{1}\right)+\beta_{2} E x p
\end{aligned}
$$

## Detecting Sex Discrimination

## Detecting Sex Discrimination

$$
\text { Salary }_{i}=\beta_{0}+\beta_{1} \text { Sex }_{i}+\beta_{2} \operatorname{Exp}+\epsilon_{i}
$$

| Regression Statistics |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Multiple R | 0.701 |  |  |  |  |  |
| R Square | 0.491 |  |  |  |  |  |
| Adjusted R Square | - 0.486 |  |  |  |  |  |
| Standard Error | 8.070 |  |  |  |  |  |
| Observations | 208 |  |  |  |  |  |
| ANOVA |  |  |  |  |  |  |

| Residual | 205.000 | 13350.839 | 65.126 |  |  |  |
| Total | 207.000 | 26227.107 |  |  |  |  |
|  | Coefficient: | Standard Error | $t$ Stat | $P$-value | Lower 95\% | Upper 95\% |
| Intercept | 27.812 | 1.028 | 27.057 | 0.000 | 25.785 | 29.839 |
| Sex | 8.012 | 1.193 | 6.715 | 0.000 | 5.660 | 10.364 |
| Exp | 0.981 | 0.080 | 12.221 | 0.000 | 0.823 | 1.139 |

Salary $_{i}=27+8$ Sex $_{i}+0.98$ Exp $_{i}+\epsilon_{i}$

## Detecting Sex Discrimination

$$
\text { Salary }_{i}= \begin{cases}27+0.98 \text { Exp }_{i}+\epsilon_{i} & \text { females } \\ 35+0.98 \text { Exp }_{i}+\epsilon_{i} & \text { males }\end{cases}
$$

## More than Two Categories

We can use dummy variables in situations in which there are more than two categories. Dummy variables are needed for each category except one, designated as the "base" category.

Why? Remember that the numerical value of each category has no quantitative meaning!

## Example: House Prices

We want to evaluate the difference in house prices in a couple of different neighborhoods.

|  | Nbhd | SqFt | Price |
| :--- | ---: | ---: | ---: |
| 1 | 2 | 1.79 | 114.3 |
| 2 | 2 | 2.03 | 114.2 |
| 3 | 2 | 1.74 | 114.8 |
| 4 | 2 | 1.98 | 94.7 |
| 5 | 2 | 2.13 | 119.8 |
| 6 | 1 | 1.78 | 114.6 |
| 7 | 3 | 1.83 | 151.6 |
| 8 | 3 | 2.16 | 150.7 |

## Example: House Prices

Let's create the dummy variables $d n 1, d n 2$ and $d n 3 \ldots$

|  | Nbhd | SqFt | Price | dn1 |  | dn2 |
| :--- | ---: | ---: | ---: | :--- | :--- | :--- |
| dn3 |  |  |  |  |  |  |
| 1 | 2 | 1.79 | 114.3 | 0 | 1 | 0 |
| 2 | 2 | 2.03 | 114.2 | 0 | 1 | 0 |
| 3 | 2 | 1.74 | 114.8 | 0 | 1 | 0 |
| 4 | 2 | 1.98 | 94.7 | 0 | 1 | 0 |
| 5 | 2 | 2.13 | 119.8 | 0 | 1 | 0 |
| 6 | 1 | 1.78 | 114.6 | 1 | 0 | 0 |
| 7 | 3 | 1.83 | 151.6 | 0 | 0 | 1 |
| 8 | 3 | 2.16 | 150.7 | 0 | 0 | 1 |

## Example: House Prices

$$
\text { Price }_{i}=\beta_{0}+\beta_{1} d n 1_{i}+\beta_{2} d n 2_{i}+\beta_{3} \text { Size }_{i}+\epsilon_{i}
$$

$$
\begin{array}{rll}
E[\text { Price } \mid d n 1=1, \text { Size }] & =\beta_{0}+\beta_{1}+\beta_{3} \text { Size } & (\text { Nbhd } 1) \\
E[\text { Price } \mid d n 2=1, \text { Size }] & =\beta_{0}+\beta_{2}+\beta_{3} \text { Size } & (\text { Nbhd } 2) \\
E[\text { Price } \mid d n 1=0, d n 2=0, \text { Size }] & =\beta_{0}+\beta_{3} \text { Size } & (\text { Nbhd } 3)
\end{array}
$$

## Example: House Prices

$$
\text { Price }=\beta_{0}+\beta_{1} d n 1+\beta_{2} d n 2+\beta_{3} \text { Size }+\epsilon
$$

$$
\text { Price }=-10.09+\text { 70.23Size }+\epsilon
$$

## Example: House Prices

## Back to the Sex Discrimination Case

Does it look like the effect of experience on salary is the same for males and females?

## Back to the Sex Discrimination Case

Could we try to expand our analysis by allowing a different slope for each group?

Yes... Consider the following model:

$$
\text { Salary }_{i}=\beta_{0}+\beta_{1} \text { Exp }_{i}+\beta_{2} \operatorname{Sex}_{i}+\beta_{3} \text { Exp }_{i} \times \operatorname{Sex}_{i}+\epsilon_{i}
$$

For Females:

$$
\text { Salary }_{i}=\beta_{0}+\beta_{1} \text { Exp }_{i}+\epsilon_{i}
$$

For Males:

$$
\text { Salary }_{i}=\left(\beta_{0}+\beta_{2}\right)+\left(\beta_{1}+\beta_{3}\right) \text { Exp }_{i}+\epsilon_{i}
$$

## Sex Discrimination Case

How does the data look like?

## Sex Discrimination Case

Salary $=\beta_{0}+\beta_{1} \operatorname{Sex}+\beta_{2} \operatorname{Exp}+\beta_{3} \operatorname{Exp} * \operatorname{Sex}+\epsilon$

| Regression Statistics |  |
| :--- | ---: |
| Multiple R | 0.7991 |
| R Square | 0.6386 |
| Adjusted R Square | 0.6333 |
| Standard Error | 6.8163 |
| Observations | 208 |

ANOVA

|  | $d f$ |  | $S S$ | $M S$ | $F$ |
| :--- | ---: | :---: | :---: | :---: | :---: |
| Regression | 3 | 16748.875 | 5582.958 | 120.162 | Significance $F$ |
| Residual | 204 | 9478.2322 | 46.46192 |  |  |
| Total | 207 | 26227.107 |  |  |  |

|  | Coefficients itandard Errc | Stat | P-value | Lower 95\% | Upper 95\% |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
| Intercept | 34.528 | 1.138 | 30.342 | 0.000 | 32.285 | 36.772 |
| Sex | -4.098 | 1.666 | -2.460 | 0.015 | -7.383 | -0.814 |
| Exp | 0.280 | 0.102 | 2.733 | 0.007 | 0.078 | 0.482 |
| Sex*Exp | 1.248 | 0.137 | 9.130 | 0.000 | 0.978 | 1.517 |

$$
\text { Salary }=34-4 S e x+0.28 E x p+1.24 E x p * S e x+\epsilon
$$

## Sex Discrimination Case

Is this good or bad news for the plaintiff?

## Variable Interaction

So, the effect of experience on salary is different for males and females... in general, when the effect of the variable $X_{1}$ onto $Y$ depends on another variable $X_{2}$ we say that $X_{1}$ and $X_{2}$ interact with each other.

We can extend this notion by the inclusion of multiplicative effects through interaction terms.

$$
\begin{gathered}
Y=\beta_{0}+\beta_{1} X_{1}+\beta_{2} X_{2}+\beta_{3}\left(X_{1} X_{2}\right)+\varepsilon \\
\frac{\partial E\left[Y \mid X_{1}, X_{2}\right]}{\partial X_{1}}=\beta_{1}+\beta_{3} X_{2}
\end{gathered}
$$

We will pick this up in our next section...

## Example: College GPA and Age

Consider the connection between college and MBA grades:
A model to predict McCombs GPA from college GPA could be

$$
G P A^{M B A}=\beta_{0}+\beta_{1} G P A^{B a c h}+\varepsilon
$$

|  | Estimate | Std.Error | t value | $\operatorname{Pr}(>\|\mathrm{t}\|)$ |
| :---: | :---: | :---: | :---: | :---: |
| BachGPA | 0.26269 | 0.09244 | 2.842 | $0.00607 * *$ |

For every 1 point increase in college GPA, your expected GPA at McCombs increases by about .26 points.

## College GPA and Age

However, this model assumes that the marginal effect of College GPA is the same for any age.

It seems that how you did in college should have less effect on your MBA GPA as you get older (farther from college).

We can account for this intuition with an interaction term:

$$
G P A^{M B A}=\beta_{0}+\beta_{1} G P A^{\text {Bach }}+\beta_{2}\left(\text { Age } \times G P A^{\text {Bach }}\right)+\varepsilon
$$

Now, the college effect is $\frac{\partial E\left[G P A^{M B A} \mid G P A^{B a c h} A g e\right]}{\partial G P A^{B a c h}}=\beta_{1}+\beta_{2}$ Age.
Depends on Age!

## College GPA and Age

$$
G P A^{M B A}=\beta_{0}+\beta_{1} G P A^{\text {Bach }}+\beta_{2}\left(\text { Age } \times G P A^{\text {Bach }}\right)+\varepsilon
$$

Here, we have the interaction term but do not the main effect of age... what are we assuming?

|  | Estimate | Std.Error | t value | $\operatorname{Pr}(>\|\mathrm{t}\|)$ |
| :---: | ---: | ---: | :---: | :--- |
| BachGPA | 0.455750 | 0.103026 | 4.424 | $4.07 \mathrm{e}-05 * *$ |
| BachGPA:Age | -0.009377 | 0.002786 | -3.366 | $0.00132 * *$ |

## College GPA and Age

Without the interaction term

- Marginal effect of College GPA is $b_{1}=0.26$.

With the interaction term:

- Marginal effect is $b_{1}+b_{2}$ Age $=0.46-0.0094$ Age .

| $\frac{\text { Age }}{25}$ |  |
| :---: | :---: |
| 30 | 0.22 |
| 35 | 0.17 |
| 40 | 0.13 |
|  | 0.08 |
