1 Description of Datasets and Competing Methods

The list of datasets and competing methods are presented in Tables 1 and 2 respectively.

Figure 1 shows simulation results on the value-weighted datasets. The results are qualitatively similar to those in Figure 3 in the manuscript.

Figure 2 shows how the average one-year Sharpe ratio of AlphaRob varies with the training sample size $n$ (results are on real-world monthly returns and not simulated returns). For comparison, we also show the results for CS, Min Var (NLS), and Min Var (L2). AlphaRob generally has the best Sharpe ratio or is close to the best. The sole exception is again the 10FFW dataset. We note that for small $n$ and large $p$, the robust optimization of CS becomes infeasible for the parameter values suggested by Ceria and Stubbs (2006).

2 Proofs of Theorems 1 to 6.

In the following, we will abbreviate $E_{D_n}[\cdot]$ to $E_n[\cdot]$ and $Var_{D_n}(\cdot)$ to $Var_n(\cdot)$. 
Dataset | Abbreviation | p |
--- | --- | --- |
Six portfolios of firms sorted by size and book-to-market | 6FFEW, 6FFVW | 6 |
Ten industry portfolios representing U.S. stock market | 10FFEW, 10FFVW | 10 |
Twenty-five portfolios of firms sorted by size and book-to-market | 25FFEW, 25FFVW | 25 |
Forty-eight industry portfolios representing U.S. stock market | 48FFEW, 48FFVW | 48 |
One hundred portfolios of firms sorted by size and book-to-market | 100FFEW, 100FFVW | 96 |
Top 200 market-value individual stocks with annual updates | 200Stocks | 200 |
Top 500 market-value individual stocks with annual updates | 500Stocks | 500 |

Table 1: List of Datasets: We use EW (equally-weighted) and VW (value-weighted) to indicate the corresponding weighting type in the abbreviation. For 100FFEW and 100FFVW, we ignore 4 assets with missing values in the data, so $p = 96$.

Table 2: List of competing methods: Methods whose parameters need to be set using out-of-sample data are starred.
Figure 1: Sharpe ratios after simulating returns for different number of assets. The two columns show simulations using a Gaussian distribution and a heavy-tailed t-distribution respectively.
Figure 2: Average one-year Sharpe ratios as a function of the training size $n$. For some datasets and training sizes, the CS method gave no results and hence is not shown.
Proof of Theorem 1. From Eq. 1 and the definition of $x$,

$$S_x(x) = \frac{E_{D_n,r}[w^T r]}{\sqrt{Var_{D_n,r}[w^T r]}}$$

where $w = \Sigma^{-1/2}x = \frac{\Sigma^{-1/2}x}{m^T x}$. 

Here $D_n$ consists of $n$ i.i.d. samples from a distribution $f(.)$, $r$ is another independent sample drawn from $f(.)$, and $\mu$ and $\Sigma$ are the mean and covariance matrix under $f(.)$. Now,

$$E_{D_n,r}[w^T r] = E_nE_r[w^T r] = E_n[w^T \mu] = E_n\left[\frac{x^T \Sigma^{-1/2} \mu}{1^T \Sigma^{-1/2} x}\right] = E_n\left[\frac{x^T z}{m^T x}\right].$$

Also,

$$Var(w^T r) = E_n\left[Var_r(w^T r)\right] + Var_n\left(E_r[w^T r]\right)$$

$$= E_n\left[w^T \Sigma w\right] + Var_n\left(w^T \mu\right)$$

$$= E_n\left[\frac{x^T x}{(m^T x)^2}\right] + Var_n\left(\frac{x^T z}{m^T x}\right).$$

The theorem statement follows. \qed

Proof of Theorem 2. The estimated mean asset return $\hat{\mu}$ is the average of $n$ independent and identically distributed returns from a distribution with mean $\mu$ and covariance $\Sigma$. So, $E[\hat{z}] = \Sigma^{-1/2} \mu = z$ and $Var(\hat{z}) = (1/n) \cdot I_{p \times p}$, where $I_{p \times p}$ is the identity matrix of that size. Since $x = m + \alpha \cdot \hat{z}$, we have $E_n[x] = m + \alpha \cdot z = \chi$ and $Var_n(x) = \frac{\alpha^2}{n} \cdot I_{p \times p}$. Now we do a Taylor expansion of the function $f(x) = (z^T x)/(m^T x)$ around $x = \chi$ and then take expectations. After some algebraic manipulations, we get

$$E_n\left[\frac{z^T x}{m^T x}\right] = \frac{z^T \chi}{m^T \chi} + \frac{\alpha^3 \left(\|m\|^2\|z\|^2 - s^2\right)}{n \left(m^T \chi\right)^3} + o\left(\frac{1}{n}\right).$$

Here, we use the fact that higher-order moments of $\hat{z}$ are $o(1/n)$. By another Taylor expansion of
the function \( f(x) = \left( \frac{z^T x}{m^T x} \right)^2 \) around \( x = \chi \) and taking expectations, we get

\[
E_n \left[ \left( \frac{z^T x}{m^T x} \right)^2 \right] = \left( \frac{z^T \chi}{m^T \chi} \right)^2 \left[ 1 + \frac{\alpha^2}{n} \left\{ \frac{\|z\|^2}{(m^T \chi)^2} - \frac{4s}{(z^T \chi)(m^T \chi)} + \frac{3\|m\|^2}{(m^T \chi)^2} \right\} \right] + o\left( \frac{1}{n} \right)
\]

\[
\Rightarrow \text{Var}_n \left( \frac{z^T x}{m^T x} \right) = E_n \left[ \left( \frac{z^T x}{m^T x} \right)^2 \right] - \left( E_n \left[ \frac{z^T x}{m^T x} \right] \right)^2
\]

\[
= \frac{\alpha^2}{n} \cdot \left( \frac{\|m\|^2\|z\|^2 - s^2}{(m^T \chi)^2} \right) \|\chi\|^2 + o\left( \frac{1}{n} \right).
\]

A Taylor expansion of the function \( f(x) = \left( \frac{x^T x}{m^T x} \right)^2 \) around \( x = \chi \) yields

\[
E_n \left[ \frac{x^T x}{(m^T x)^2} \right] = \frac{\|\chi\|^2}{(m^T \chi)^2} + \frac{\alpha^2}{n (m^T \chi)^2} \left( p - 4 + \frac{3\|m\|^2\|\chi\|^2}{(m^T \chi)^2} \right) + o\left( \frac{1}{n} \right)
\]

\[
= \frac{\|\chi\|^2}{(m^T \chi)^2} + \frac{\alpha^2}{n (m^T \chi)^2} \left( p - 1 + \frac{3\alpha^2(\|m\|^2\|z\|^2 - s^2)}{(m^T \chi)^2} \right) + o\left( \frac{1}{n} \right).
\]

Combining these and applying Theorem 1, we get

\[
S_x(x) = \frac{E_n \left[ \frac{z^T x}{m^T x} \right]}{\sqrt{E_n \left[ \frac{x^T x}{(m^T x)^2} \right] + \text{Var}_n \left( \frac{z^T x}{m^T x} \right)}}
\]

\[
= \frac{(z^T \chi) + \frac{\alpha^3}{n} \cdot \left( \frac{\|m\|^2\|z\|^2 - s^2}{(m^T \chi)^2} \right)}{\sqrt{\|\chi\|^2 + \frac{\alpha^2}{n} \left[ p - 1 + \frac{\|m\|^2\|z\|^2 - s^2 \cdot (3\alpha^2 + \|\chi\|^2)}{(m^T \chi)^2} \right]}} + o\left( \frac{1}{n} \right).
\]

\[\square\]

**Proof of Theorem 3.** We will first show that

\[
0 \leq \frac{\alpha^3}{n} \cdot \left( \frac{\|m\|^2\|z\|^2 - s^2}{(m^T \chi)^2} \right) \leq \frac{1/\theta^2 - 1}{n\|z\|^2}
\]

\[
(1 - \theta^2)\|z\|^2 \leq \frac{\|m\|^2\|z\|^2 - s^2 \cdot (3\alpha^2 + \|\chi\|^2)}{(m^T \chi)^2} \leq \frac{1}{\theta^2} \cdot \frac{(\|z\|^2 + 3)}{\theta^2}.
\]
Using $\chi = m + \alpha \cdot z$, we have

$$\|\chi\|^2 = \|m\|^2 + 2\alpha \theta \|m\| \|z\| + \alpha^2 \|z\|^2$$

$$m^T \chi = \|m\|^2 + \alpha s$$

$$z^T \chi = s + \alpha \|z\|^2.$$

Using $m^T z = s = \|m\| \|z\| \theta$, we have

$$\frac{\alpha^3}{n} \cdot \frac{(\|m\|^2 \|z\|^2 - s^2)}{(m^T \chi)^2 (z^T \chi)} = \frac{\|m\|^2 \|z\|^2 (1 - \theta^2)}{n (s + \|m\|^2 / \alpha)^2 (\|z\|^2 + s / \alpha)} \in \left[0, \frac{(1/\theta^2 - 1)}{n \|z\|^2}\right].$$

which proves the first bound. Also,

$$\frac{(\|m\|^2 \|z\|^2 - s^2) \cdot (3 \alpha^2 + \|\chi\|^2)}{(m^T \chi)^2} = \frac{\|z\|^2 (1 - \theta^2)(\|m\|^2 + 2\alpha \|m\| \|z\| \theta + \alpha^2 (3 + \|z\|^2))}{(\|m\| + \alpha \|z\|)^2}

= \|z\|^2 (1 - \theta^2) \left(1 + \frac{(3 + \|z\|^2 (1 - \theta^2))}{(\|m\|/\alpha + \theta \|z\|)^2}\right)

\in \left[(1 - \theta^2) \|z\|^2, (1 - \theta^2) \cdot \frac{(3 + \|z\|^2)}{\theta^2}\right],$$

proving the second bound. Using these two bounds in Theorem 2 followed by algebraic manipulations yields the desired result.

**Proof of Theorem 4.** The numerator of Eq. 9 does not depend on $\alpha$. We will show that the denominator has a single minimum at $\alpha = \alpha^*$. The denominator equals $1 + q(\alpha \ | \ |z|, \theta)$ (Eq. 10):

$$q(\alpha \ | \ |z|, \theta) = \frac{(\|m\|^2 \|z\|^2 - s^2) + \alpha^2 (p/n) \|z\|^2}{(s + \alpha \|z\|^2)^2}

= \frac{(1 - \theta^2) + \alpha^2 A}{(\theta + \alpha B)^2}$$

where $A = \frac{p}{n \|m\|^2}$, $B = \frac{\|z\|}{\|m\|}$.

Taking the derivative with respect to $\alpha$,

$$\frac{d}{d\alpha} q(\alpha \ | \ |z|, \theta) = 2 \cdot \frac{\alpha A \theta - (1 - \theta^2) B}{(\theta + \alpha B)^3}. \quad (2)$$

Since $\theta > 0$, $\alpha \geq 0$, and $B \geq 0$, this has a single inflection point at $\alpha = \alpha^*$ as defined in the theorem statement. Also, the derivative is positive for $\alpha > \alpha^*$ and negative for $\alpha < \alpha^*$, so this is a
minimum. The theorem follows.

**Proof of Theorem 5.** We have \( E[\hat{z}] = z \) and \( \text{Var}(\hat{z}) = (1/n) \cdot I_{p \times p} \). By a Taylor expansion of the function \( f(x) = \sqrt{x^T x} \) around \( x = z \) and taking expectations, we get

\[
E\|\hat{z}\| = \|z\| + \frac{1}{2} \cdot E \left[ (\hat{z} - z)^T \frac{1}{\|z\|} \left( I_{p \times p} - \frac{1}{\|z\|^2} \cdot zz^T \right) (\hat{z} - z) \right] + o\left( \frac{1}{n} \right)
\]

\[
= \|z\| + \frac{1}{2\|z\|} \cdot \text{Trace} \left[ \left( I_{p \times p} - \frac{1}{\|z\|^2} \cdot zz^T \right) \cdot \text{Var}(\hat{z}) \right] + o\left( \frac{1}{n} \right)
\]

\[
= \|z\| + \frac{p - 1}{2n\|z\|} + o\left( \frac{1}{n} \right).
\]

Similarly, taking a Taylor expansion of the function \( f(x) = (m^T x) / (\|m\| \|x\|) \) around \( x = z \) and taking expectations, we get

\[
E\hat{\theta} = \theta - \frac{(p - 1) \cdot m^T z}{2n\|m\| \|z\|^2} + o\left( \frac{1}{n} \right) = \theta \left( 1 - \frac{p - 1}{2n\|z\|^2} \right) + o\left( \frac{1}{n} \right).
\]

This proves the theorem.

**Proof of Theorem 6.** By Eq. 11, any element in \( \{\|z\| \mid (\|z\|, \theta) \in \Gamma_\gamma\} \) must satisfy \( \|z\| = \gamma p \cdot (n\|m\| \cdot (1/\theta_\gamma - \theta_\gamma))^{-1} \), which proves the first statement.

Define \( f_\gamma(\alpha, \theta) = h(\alpha \mid \|z\|, \theta) \) as a function of \( \alpha \) and \( \theta \), with \( \|z\| \) fixed to the unique value that gives \( \alpha^*(\|z\|, \theta) = \gamma \). Also, let \( g_\gamma(\alpha, \theta) = \left. \frac{d}{d\theta} \log (1 + q(\alpha \mid \|z\|, \theta)) \right|_{\theta_\gamma} \). The second statement of the theorem will be proved if we show that \( \frac{d}{d\theta} f_\gamma(\alpha, \theta) \geq 0 \) for any \( \alpha \geq 0 \). Now,

\[
\frac{d}{d\theta} f_\gamma(\alpha, \theta) \geq 0 \iff \frac{d}{d\theta} \log (1 + q(\gamma \mid \|z\|, \theta)) - \frac{d}{d\theta} \log (1 + q(\alpha \mid \|z\|, \theta)) \geq 0 \iff g_\gamma(\gamma, \theta) \geq g_\gamma(\alpha, \theta).
\]

To show Eq. 3, we will show that for any fixed \( \theta \), \( \alpha = \gamma \) is a maximum of \( g_\gamma(\alpha, \theta) \).
First, observe that

\[
\frac{d}{d\alpha} g_\gamma(\alpha, \theta) = \frac{d^2}{d\alpha d\theta} \log (1 + q(\alpha \mid \|z\|, \theta))
\]

\[
= \frac{d}{d\theta} \left( \frac{2(\alpha - \gamma) A \theta}{(\theta + \alpha B)^3 (1 + q(\alpha \mid \|z\|, \theta))} \right)
\]

\[
= 2(\alpha - \gamma) A \cdot \frac{d}{d\theta} \left( \frac{\theta}{(\theta + \alpha B)^3 (1 + q(\alpha \mid \|z\|, \theta))} \right)
\]

(4)

where the second equality is obtained from Eqs. 2 and 11. Note that \(B\) is a function of \(\|z\|\), which itself is a function of \(\gamma\) and \(\theta\). Thus, \(\left[ \frac{d}{d\alpha} g_\gamma(\alpha, \theta) \right]_{\alpha=\gamma} = 0\), so \(g_\gamma(\alpha, \theta)\) has a mode at \(\alpha = \gamma\) for any \(\theta\). To show that this mode is a maximum, we will show that \(\frac{d}{d\alpha} g_\gamma(\alpha, \theta)\) is positive for \(0 < \alpha < \gamma\) and negative for \(\alpha > \gamma\).

Let us fix \(\alpha > 0\), and use \(q(\theta) = q(\alpha \mid \|z\|, \theta)\) and \(B(\theta)\) to denote the fact that \(q(\cdot \mid \|z\|, \theta)\) and \(B(\cdot)\) are functions of \(\theta\). Let \(C(\theta) = (\theta + \alpha B(\theta))^3 (1 + q(\theta))\). Continuing from Eq. 4,

\[
\frac{d}{d\theta} \left( \frac{\theta}{(\theta + \alpha B)^3 (1 + q(\theta))} \right) = \left( \frac{\theta + \alpha B(\theta)}{C(\theta)} \right)^2 D(\theta)
\]

where \(D(\theta) = (\theta + \alpha B(\theta))(1 + q(\theta)) - 3\theta(1 + q(\theta)) \cdot \frac{d}{d\theta}(\theta + \alpha B(\theta)) - \theta(\theta + \alpha B(\theta)) \cdot \frac{d}{d\theta}q(\theta)\)

Now, by Eqs. 11 and 1, we have

\[
B(\theta) = \gamma A \left( \frac{\theta}{1 - \theta^2} \right)
\]

\[
\Rightarrow \frac{d}{d\theta} (\theta + \alpha \cdot B(\theta)) = 1 + \gamma \alpha A \cdot \frac{1 + \theta^2}{(1 - \theta^2)^2} = 1 + \frac{\alpha B(\theta)}{\theta} \left( 1 + \frac{2\theta^2}{1 - \theta^2} \right)
\]

(5)

\[
\frac{d}{d\theta} q(\theta) = \frac{d}{d\theta} \left( \frac{1 - \theta^2 + \alpha^2 A}{(\theta + \alpha B(\theta))^2} \right) = -2 \frac{2\theta}{(\theta + \alpha B(\theta))^2} \cdot \frac{d}{d\theta}(\theta + \alpha B(\theta)) - 2 \left( \frac{q(\theta)}{\theta + \alpha B(\theta)} \right) \cdot \frac{d}{d\theta}(\theta + \alpha B(\theta)).
\]

(6)
Using these in the formula for $D(\theta)$, we have

$$D(\theta) = (\theta + \alpha B(\theta))(1 + q(\theta)) + \frac{2\theta^2}{\theta + \alpha B(\theta)} - \theta (3 + q(\theta)) \cdot \frac{d}{d\theta} (\theta + \alpha B(\theta))$$

$$= (1 + q(\theta)) \left( \theta + \alpha B(\theta) - \theta \cdot \frac{d}{d\theta} (\theta + \alpha B(\theta)) \right) + \frac{2\theta^2}{\theta + \alpha B(\theta)} - 2\theta \cdot \frac{d}{d\theta} (\theta + \alpha B(\theta))$$

$$= (1 + q(\theta)) \left( -\frac{2\alpha \theta^2 B(\theta)}{1 - \theta^2} \right) + \frac{2\theta^2}{\theta + \alpha B(\theta)} - 2\theta - 2\alpha B(\theta) \left( 1 + \frac{2\theta^2}{1 - \theta^2} \right)$$

$$= -3 \left( \frac{\alpha \theta^2 B(\theta)}{1 - \theta^2} \right) (3 + q(\theta)) - 2 \left( \frac{\alpha B(\theta)(2\theta + \alpha B(\theta))}{\theta + \alpha B(\theta)} \right)$$

$$< 0,$$

where the first equality follows from Eq. 6, the third equality from Eq. 5, and the inequality from $q(\theta) > 0$, since $\theta \leq 1$ and $\alpha > 0$. Using this in Eq. 4 shows that $\frac{d}{d\alpha} g_{\gamma}(\alpha, \theta)$ is positive for $0 < \alpha < \gamma$ and negative for $\alpha > \gamma$. This completes the proof of the second statement. \qed 

3 Proof of Theorem 7.

We first prove several helpful lemmas. Define $u(t)$ and $v(t)$ to be the minimum and maximum of $h\left(\alpha(t) \mid \gamma_{lo}^{(t+1)}\right)$ and $h\left(\alpha(t) \mid \gamma_{hi}^{(t+1)}\right)$ (see Figure 2). Note that $\kappa(t), \kappa^{(t+1)}, u(t), \text{ and } v(t)$ are all less than or equal to zero.

**Lemma 1.** If $\theta_+ > 0$, $\|z\|_+ < \infty$, and $0 \leq \alpha \leq \max(\mathcal{I}_\gamma)$, there exist constants $C_1 > 0$ and $C_2 > 0$ that depend on $\mathcal{I}_{\|z\|}$ and $\mathcal{I}_\theta$ such that $C_1 \cdot |\alpha - \gamma| \leq \left| \frac{d}{d\alpha} h(\alpha \mid \gamma) \right| \leq C_2$.

**Proof.**

$$\frac{d}{d\alpha} h(\alpha \mid \gamma) = \frac{d}{d\alpha} \log \left( \frac{1 + q(\gamma \mid \|z\|, \theta)}{1 + q(\alpha \mid \|z\|, \theta)} \right) = \frac{2(\alpha - \gamma)A\theta}{(1 + q(\alpha \mid \|z\|, \theta))(\theta + \alpha B)^3}.$$  

The desired bounds follows from $\theta \geq \theta_+ > 0$, $\|z\| \leq \|z\|_+ < \infty$, and $0 \leq \alpha \leq \max(\mathcal{I}_\gamma) = \alpha^*(\|z\|_+, \theta_-) < \infty$. \qed
Lemma 2. We have:

\[ \forall t', \kappa'(t') \geq \kappa_{rob}, \quad u(t) \leq \kappa_{rob}, \quad \kappa'(t+1) \leq v(t) \leq \kappa(t). \]

Proof. First we will show that \( \kappa'(t') \geq \kappa_{rob} \). Suppose this is not the case. Then, \( \alpha'(t') \neq \alpha_{rob} \) and \( h(\alpha'(t') \mid \gamma(t')) = h(\alpha'(t') \mid \gamma_{hi}(t')) = \kappa'(t') < \kappa_{rob} \). If \( \alpha'(t') < \alpha_{rob} \), then \( h(\alpha_{rob} \mid \gamma(t')) < h(\alpha(t') \mid \gamma_{lo}(t')) < \kappa_{rob} \), where the first inequality follows from unimodality of \( h(\alpha \mid \gamma_{lo}(t')) \) (Theorem 4) and the fact that it achieves its maximum at \( \gamma_{lo}(t') < \alpha(t') < \alpha_{rob} \). But by definition, \( \kappa_{rob} = \min_{\gamma} h(\alpha_{rob} \mid \gamma) \). This leads to a contradiction. A similar argument holds when \( \alpha'(t') > \alpha_{rob} \).

Hence, \( \kappa'(t') \geq \kappa_{rob} \).

If \( u(t) > \kappa_{rob} \), then \( v(t) > u(t) > \kappa_{rob} \), by the definition of \( u(t) \) and \( v(t) \). By the definitions of \( \gamma_{lo}(t+1) \) and \( \gamma_{hi}(t+1) \) in Algorithm 1, the above statement implies that \( \min_{\alpha} h(\alpha(t) \mid \gamma) > \kappa_{rob} \) (recall that \( h(\alpha \mid \gamma) \leq 0 \) always). This contradicts the definition of \( \alpha_{rob} \) and \( \kappa_{rob} \). Hence, \( u(t) \leq \kappa_{rob} \).

Now suppose, without loss of generality, that the maximum of \( h(\alpha(t) \mid \gamma_{lo}(t+1)) \) and \( h(\alpha(t) \mid \gamma_{hi}(t+1)) \) was achieved by the former. Then, from the definition of \( \gamma_{lo}(t+1) \), we have \( v(t) = \min_{\gamma \leq \alpha(t)} h(\alpha(t) \mid \gamma) \leq h(\alpha(t) \mid \gamma_{lo}(t)) = \kappa(t) \). Also, \( \kappa(t+1) \) must be between \( u(t) \) and \( v(t) \), since \( \kappa(t+1) \) is achieved at the intersection of the curves indexed by \( \gamma_{lo}(t+1) \) and \( \gamma_{hi}(t+1) \). Hence, we must have \( v(t) \geq \kappa(t+1) \). This proves the lemma. \( \square \)

Lemma 3. Under the conditions of Lemma 1, for any feasible \( \alpha, \alpha', \) and \( \gamma \), we have

\[ |\alpha - \alpha'| \geq \frac{|h(\alpha \mid \gamma) - h(\alpha' \mid \gamma)|}{C_2}. \]

In particular,

\[ \min \left( |\alpha(t) - \gamma_{lo}(t+1)|, |\alpha(t) - \gamma_{hi}(t+1)| \right) \geq \frac{|v(t)|}{C_2}, \quad |\alpha(t+1) - \alpha(t)| \geq \frac{v(t) - u(t)}{2 \cdot C_2}. \]

Proof. The first statement follows from \( |h(\alpha \mid \gamma) - h(\alpha' \mid \gamma)| = \left| \int_{\alpha}^{\alpha'} \frac{d}{dx} h(x \mid \gamma) \, dx \right| \leq C_2 \cdot |\alpha - \alpha'| \),
where we used Lemma 1 in the inequality. Applying this twice, we find

\[ |\alpha(t) - \gamma^{(t+1)}_{lo}| \geq \frac{|h(\alpha(t) | \gamma^{(t+1)}_{lo}) - h(\gamma^{(t+1)}_{lo} | \gamma^{(t+1)}_{lo})|}{C_2} = \frac{|h(\alpha(t) | \gamma^{(t+1)}_{lo})|}{C_2}, \]

\[ |\alpha(t) - \gamma^{(t+1)}_{hi}| \geq \frac{|h(\alpha(t) | \gamma^{(t+1)}_{hi})|}{C_2}, \]

\[ \Rightarrow \min(|\alpha(t) - \gamma^{(t+1)}_{lo}|, |\alpha(t) - \gamma^{(t+1)}_{hi}|) \geq \min\left(\frac{|h(\alpha(t) | \gamma^{(t+1)}_{lo})|}{C_2}, \frac{|h(\alpha(t) | \gamma^{(t+1)}_{hi})|}{C_2}\right) = \frac{|v(t)|}{C_2}, \]

proving the second statement. Repeating this argument, we see

\[ |\alpha^{(t+1)}(t) - \alpha^{(t)}| \geq \frac{|h(\alpha^{(t+1)} | \gamma^{(t+1)}_{lo}) - h(\alpha^{(t)} | \gamma^{(t+1)}_{lo})|}{C_2} = \frac{|v(t) - \kappa^{(t+1)}_{lo}|}{C_2}, \]

and \[ |\alpha^{(t+1)}(t) - \alpha^{(t)}| \geq \frac{|h(\alpha^{(t+1)} | \gamma^{(t+1)}_{hi}) - h(\alpha^{(t)} | \gamma^{(t+1)}_{hi})|}{C_2} = \frac{\kappa^{(t+1)}_{hi} - u(t)}{C_2}, \]

where we assumed without loss of generality that \( v(t) = h(\alpha^{(t)} | \gamma^{(t+1)}_{lo}) \), and we used the fact that \( u(t) \leq \kappa_{rob} \leq \kappa^{(t+1)} \leq v(t) \) (Lemma 2). Summing these two statements, \( |\alpha^{(t+1)} - \alpha^{(t)}| \geq \frac{v(t) - u(t)}{2C_2}. \)

**Proof of Theorem 7.** The fact that \( \kappa_{rob} \leq \kappa^{(t')} \leq \kappa^{(1)} \leq 0 \) follows from Lemma 2. Since the curves are unimodal (Theorem 4), \( \kappa^{(1)} = 0 \) iff \( \gamma^{(1)}_{lo} = \gamma^{(1)}_{hi} \). By construction, this happens only if the interval \( I_\gamma \) is degenerate. Now assume, without loss of generality, that \( v(t) = h(\alpha^{(t)} | \gamma^{(t+1)}_{lo}) \).

This implies that \( \alpha^{(t+1)} \geq \alpha^{(t)} \), since \( \alpha^{(t+1)} \) is the intersection of the curves indexed by \( \gamma^{(t+1)}_{lo} \) and
\[ \gamma_{hi}^{(t+1)} \] (see Figure 2). Then,

\[
\kappa^{(t+1)} = \kappa^{(t)} + \int_{\alpha^{(t)}}^{\alpha^{(t+1)}} \frac{d}{d\alpha} h \left( \alpha \mid \gamma_{lo}^{(t+1)} \right)
\]

\[
\leq \kappa^{(t)} - |\alpha^{(t)} - \alpha^{(t+1)}| \cdot C_1 \cdot |\alpha^{(t)} - \gamma_{lo}^{(t+1)}| \]  \hspace{1cm} \text{(Lemma 1)}

\[
\leq \kappa^{(t)} - \left( \frac{v^{(t)} - u^{(t)}}{2 \cdot C_2} \right) \cdot C_1 \cdot \frac{|v^{(t)}|}{C_2} \]  \hspace{1cm} \text{(Lemma 3)}

\[
\leq \kappa^{(t)} \left( 1 + \frac{C_1 \cdot (v^{(t)} - u^{(t)})}{2 \cdot C_2^2} \right) \]  \hspace{1cm} (|v^{(t)}| = -v^{(t)} \geq -\kappa^{(t)} \text{ by Lemma 2})

\[ \Rightarrow |\kappa^{(t+1)}| \geq |\kappa^{(t)}| \left( 1 + \frac{C_1 \cdot (|\kappa_{rob}| - |v^{(t)}|)}{2 \cdot C_2^2} \right) \]  \hspace{1cm} (u^{(t)} \leq \kappa_{rob} \text{ by Lemma 2})

This shows that \(|\kappa^{(t+1)}| \geq |\kappa^{(t)}|\), since \(|\kappa_{rob}| \geq |\kappa^{(t+1)}| \geq |v^{(t)}|\) by Lemma 2. But, by Lemma 2, we also have \(\kappa^{(t+1)} \leq v^{(t)}\). So,

\[
|\kappa^{(t+1)}| \geq \max \left( |v^{(t)}|, |\kappa^{(t)}| \left( 1 + C_3 \cdot (|\kappa_{rob}| - |v^{(t)}|) \right) \right) \]  \hspace{1cm} \left( C_3 = \frac{C_1}{2 \cdot C_2^2} \right)

\[
\geq |\kappa^{(t)}| \left( 1 + C_3 \cdot \frac{|\kappa_{rob}|}{1 + C_3 \cdot |\kappa^{(t)}|} \right),
\]

where the second inequality is achieved by setting \(v^{(t)}\) to equalize both terms in the maximum. Hence,

\[
|\kappa_{rob} - |\kappa^{(t+1)}| \leq \frac{|\kappa_{rob} - |\kappa^{(t)}|}{1 + C_3 \cdot |\kappa^{(t)}|} \]  \hspace{1cm} \text{since } |\kappa^{(t+1)}| \geq |\kappa^{(t)}|.

The formula in the theorem statement follows easily. \[ \square \]
4 Combination Portfolios under the Mean-Variance Utility.

This common utility function linearly combines the mean portfolio return and its variance:

\[ \mathbb{U}_w(w) = E[w^TR] - \gamma \cdot \text{Var}(w^TR), \]  

where the parameter \( \gamma > 0 \) represents the risk-reward tradeoff.

Let \( x \) be defined as in Section 3, and let \( \mathbb{U}_x(x) \) refer to the expected utility of the portfolio \( w \) constructed from \( x \).

**Theorem 1.**

\[
\mathbb{U}_x(m + \alpha \cdot \hat{z}) = \left( \frac{z^T \chi}{m^T \chi} \right) \left[ 1 + \frac{\alpha^3}{n} \cdot \frac{(\|m\|^2\|z\|^2 - s^2)}{(m^T \chi)^2 (z^T \chi)} \right] - \frac{\gamma}{(m^T \chi)^2} \left[ \|\chi\|^2 + \frac{\alpha^2}{n} \left( (\|m\|^2\|z\|^2 - s^2) \cdot \frac{3\alpha^2 + \|\chi\|^2}{(m^T \chi)^2} \right) \right] + o \left( \frac{1}{n} \right),
\]

where \( \chi = m + \alpha \cdot z \).

Under the conditions of Theorem 3, this simplifies to

\[
\mathbb{U}_x(m + \alpha \cdot \hat{z}) \approx \frac{z^T \chi}{m^T \chi} - \gamma \cdot \frac{\|\chi\|^2 + \alpha^2 \cdot \frac{p}{n}}{(m^T \chi)^2}.
\]

The optimum is attained at

\[
\alpha_{MV}^* = \begin{cases} 
\frac{\|m\|^2}{2\gamma \left( 1 + \frac{p}{n} \cdot \left( \frac{\|m\|^2}{\|m\|^2 + \|\chi\|^2 - s^2} \right) \right)} - s, & \text{if } \gamma \left( 1 + \frac{p}{n} \cdot \left( \frac{\|m\|^2}{\|m\|^2 + \|\chi\|^2 - s^2} \right) \right) \geq \frac{s}{2} \\
\infty, & \text{otherwise}
\end{cases}
\]

This behaves quite differently from the \( \alpha^* \) for the maximum-Sharpe portfolios (Eq. 11). The maximum-Sharpe \( \alpha^* \) grows linearly with \( n \). However, for the expected utility in Eq. 7, there is a threshold behavior. When \( \gamma \geq s/2 \), \( \alpha_{MV}^* \) converges to \( \|m\|^2/(2\gamma - s) \) from below as \( n \) increases. When \( \gamma < s/2 \), \( \alpha_{MV}^* \) increases as \( n \) increases towards a threshold value, and jumps to \( \infty \) above
this threshold. This threshold is given by

\[
    n_{\text{thresh}} = \frac{2\gamma p}{(s - 2\gamma)\|z\|^2(1 - \theta^2)},
\]

where \(\theta = s/(\|m\|\|z\|)\).

This can be intuitively explained by viewing Eq. 7 as the Lagrangian of the “mean-variance” optimization problem:

\[
    \text{maximize } E[w^T r] \text{ subject to } \text{Var}(w^T r) \leq \rho, w^T 1 = 1.
\]

Larger values of \(\gamma\) correspond to tighter constraints on the variance (i.e., smaller \(\rho\), and reduces the achievable mean return. Thus, for a large enough \(\gamma\), the optimal \(\alpha_{opt}\) converges to a constant with growing \(n\). However, if \(\gamma\) is too small, the variance constraint is not active and the mean portfolio continuously grows with \(\alpha_{MV}^*\) as long as the expected return of each asset can be estimated relatively accurately (i.e., large enough \(n\)). For small \(n\), uncertainty about the expected asset returns limits the achievable return of the overall portfolio.
